4 Summary & Conclusion

< (日) × (日) × (1)

 X_1, \dots, X_n are random variables with joint distribution function F and probablity density function f.

Independence: For any multivariate distribution, the distribution can be written as:

$$F(x_1,\ldots,x_n) = \prod_{i=1}^n F(x_i),$$

$$f(x_1,\ldots,x_n) = \prod_{i=1}^n f(x_i),$$

if $x_i, i = 1, \cdots, n$ are independent.

くロッ くぼう くほう くほう 二日

 X_1, \dots, X_n are random variables with joint distribution function F and probablity density function f.

Theorem 1 (Sklar's Theorem:)

For any multivariate distribution, the distribution can be written as:

$$F(x_1,\ldots,x_n)=C(F_1(x_1),\ldots,F_n(x_n)),$$

where $C : [0,1]^n \rightarrow [0,1]$ is called a **Copula** function (**Unique**).

Remark 1

Copula enables us modeling the dependence structure separately from modeling the marginals.

Theorem (Sklar's Theorem:)

For any multivariate distribution, the distribution can be written as:

$$F(x_1,\ldots,x_n)=C(F_1(x_1),\ldots,F_n(x_n)),$$

where $C : [0,1]^n \rightarrow [0,1]$ is called a **Copula** function (**Unique**).

Corollary 2

Let
$$u_1 = F_1(x_1), \dots, u_n = F_n(x_n)$$
, and $x_1 = F_1^{-1}(u_1), \dots, x_n = F_n^{-1}(u_n)$
 $C(u_1, \dots, u_n) = F(F_1^{-1}(u_1), \dots, F_n^{-1}(u_n)),$

Definition 3

Let $\mathbf{U} = (u_1, \dots, u_n)$ has uniformly distributed marginals, i.e., $u_i \sim \mathbb{U}(0, 1), i = 1, \dots, n$, the joint cumulative distribution is called copula function:

$$C(u_1,\ldots,u_n)=P(U_1\leq u_1,\ldots,U_n\leq u_n),$$

Remark 2

A method to construct copula:

$$C(u_1,\ldots,u_n) = F(F_1^{-1}(u_1),\ldots,F_n^{-1}(u_n)),$$

One family of copula is the elliptical copula derived from the elliptical distributions

Two major copula families:

- Archimedean Copula Clayton, Gumbel, etc
- Elliptical Copula Gaussian, *t*-copula, etc.

4 Summary & Conclusion

→ < ∃ →</p>

$$I(\mathbf{x}) = \sum_{i} H(x_i) - H(\mathbf{x})$$

Theorem 4

Mutual information is the negative entropy of the corresponding copula function:

$$I(\mathbf{x}) = -H_c(\mathbf{u})$$

Definition 5 (Copula Entropy)

Let $\mathbf{x} = (x_1, \dots, x_n)$ be the random vector with marginals $\mathbf{u} = (u_1, \dots, u_n)$ and the copula density is $c(\mathbf{u})$. Copula entropy is defined as

$$H_c(\mathbf{u}) = -\int_{\mathbf{u}} c(\mathbf{u}) \log(c(\mathbf{u})) \mathrm{d}\mathbf{u}$$

< □ > < 同 > < 三 > <

Proof.

$$I(\mathbf{x}) = \int_{\mathbf{x}} p(\mathbf{x}) \log \frac{p(\mathbf{x})}{\prod_{i} p(x_{i})} d\mathbf{x}$$
$$= \int_{\mathbf{x}} c(\mathbf{u}_{\mathbf{x}}) \prod_{i} p(x_{i}) \log c(\mathbf{u}_{\mathbf{x}}) d\mathbf{x}$$
$$= \int_{\mathbf{u}_{\mathbf{x}}} c(\mathbf{u}_{\mathbf{x}}) \log c(\mathbf{u}_{\mathbf{x}}) d\mathbf{u}_{\mathbf{x}}$$
$$= -H_{c}(\mathbf{u}_{\mathbf{x}})$$

$$p(x_1,\ldots,x_n)=c(u_1,\ldots,u_n)\prod_{i=1}^n p(x_i),$$

where u_i is the marginal (CDF) of x_i .

< □ > < □ > < □ > < □ > < □ >

Figure 1: Two way of understanding MI. Left: Traditional way. Right: Copula Way

Figure 2: The relationship between the entropy of random variables, margin entropies, and the copula entropy

Chris(Ce ZHENG) (University of Lille, France

$$I(\mathbf{x}) = -H_c(\mathbf{u})$$

Remark 3

Mutual Information exactly measures the uncertainty of the dependence of random variables.

• MI used to be understood as the intersection of margin entropies. However, MI as copula entropy has no intersection with the margin entropy of each random variable

$$I(\mathbf{x}) = -H_c(\mathbf{u})$$

Remark 3

Mutual Information exactly measures the uncertainty of the dependence of random variables.

Independence between copula and margins:

 Variations of random variables can have different margin entropies that have no effect on the copula entropy, i.e., MI;
 Same margin entropy, but different copula functions, i.e., different dependence and different MI.

Estimation of Mutual Information with copula:

$$I(\mathbf{x}) = -H_c(\mathbf{u})$$

Given a data set of samples $\mathbf{X} = \{\mathbf{x}_1, \dots, \mathbf{x}_N\}$ with d dimension,

 \bullet Step 1 Determine the empirical copula density \hat{U} from X

$$\hat{\mathbf{U}}_i(j) = \frac{1}{N} \sum_{k=1}^N \mathbf{1}_{\mathbf{x}_i(k) \le \mathbf{x}_i(j)}$$

where $\mathbf{x}_i(j)$ is the *j*-th dimension of the *i*-th sample \mathbf{x}_i

• Step 2 Estimate entropy of Û.

3 Challenge

4 Summary & Conclusion

• • = • •

Blind Source Separation

Blind Source Separation (BSS) is to recover the underlying component from their mixtures, where the mixing matrix and distribution of component are unknown.

Independent Component Analysis (ICA) method:

$$\mathbf{x} = \mathbf{A}\mathbf{s} \text{ or } \hat{\mathbf{s}} = \mathbf{W}\mathbf{x}$$
$$p(\mathbf{x}) = p(\mathbf{A}\mathbf{s}) = |\det(\mathbf{W})|p(\mathbf{s})$$
$$p(\mathbf{s}) = \prod_{i=1}^{n} p(s_i)$$

where the source signal $\mathbf{s} = [s_1, \dots, s_n]$ is assumed to be **independent**, **A** and **W** = \mathbf{A}^{-1} is the mixing and demixing matrix to be solved.

Blind Source Separation

Copula Component Analysis (CCA) method: dependent source signals

PDF of the proposed model:

$$p_c(\mathbf{s}) = c(\mathbf{u}) \prod_{i=1}^n p(s_i)$$

Minimize the KL distance between the real PDF $p(\mathbf{s})$ and $p_c(\mathbf{s})$:

$$D(p||p_c) = \mathbf{E}_{p(\mathbf{s})} \log \frac{p(\mathbf{s})}{p_c(\mathbf{s})} = \mathbf{E}_{p(\mathbf{s})} \log \frac{p(\mathbf{s})}{\prod_{i=1}^n p(s_i)} - \mathbf{E}_{p(\mathbf{s})} \log c(\mathbf{u})$$

→ Ξ →

Blind Source Separation

$$D(p||p_c) = \mathbf{E}_{p(\mathbf{s})} \log \frac{p(\mathbf{s})}{\prod_{i=1}^{n} p(s_i)} - \mathbf{E}_{p(\mathbf{s})} \log c(\mathbf{u})$$
$$= I(s_1, \cdots, s_n) + H_p(c(\mathbf{u}))$$

The first term – KL distance between $p(\mathbf{x})$ and ICA model The second term – entropy of copula

Solve **W** from min $I(s_1, \cdots, s_n; \mathbf{W})$

2 Determine θ in $C(\mathbf{u}; \theta)$ from max $H_p(c(\mathbf{u}))$

4 Summary & Conclusion

Receiver Design

In a **SIMO** (1×2) system, antennas close by are more likely have the large value of interference at the same time. And the received signal is

$$\begin{cases} y_1 = s + i_1 \\ y_2 = s + i_2 \end{cases}$$

where $s \in -1, 1$.

The Log Likelihood Ratio (LLR) is

$$\Lambda(y_1, y_2) = \log \frac{f(y_1 - 1)f(y_2 - 1)c(F(y_1 - 1), F(y_2 - 1))}{f(y_1 + 1)f(y_2 + 1)c(F(y_1 + 1), F(y_2 + 1))}$$

= $\underbrace{\log \frac{f(y_1 - 1)f(y_2 - 1)}{f(y_1 + 1)f(y_2 + 1)}}_{\Lambda_{\perp}(y_1, y_2)} + \underbrace{\log \frac{c(F(y_1 - 1), F(y_2 - 1))}{c(F(y_1 + 1), F(y_2 + 1))}}_{\Lambda_{c}(y_1, y_2)}$

where $\Lambda_c(y_1, y_2)$ is the part of LLR depending on the copula and represents the dependence structure.

4 Summary & Conclusion

→ < ∃ →</p>

Diversity Combining

Selection Combining (SC): For two channels with SNR_i , i = 1, 2, for independent case we have

$$\mathbf{P_{out}} = \mathbf{P}[SNR_1 \le x, SNR_2 \le x]$$
$$= \prod_i \mathbf{P}[SNR_i < x]$$

for dependent case, we have

$$\begin{aligned} \mathbf{P}_{out} &= \mathbf{P}[SNR_1 \leq x, SNR_2 \leq x] \\ &= C(F_1(x), F_2(x)) \end{aligned}$$

where $F_1(x) = \mathbf{P}[SNR_1 \le x]$ and $F_2(x) = \mathbf{P}[SNR_2 \le x]$. Maximal Ratio Combining (MRC) in [8].

3 Challenge

4 Summary & Conclusion

Empirical Copula

Gareth Peters showed that the non-standard dependence (tail dependence) features exist between multiple frequency bands in wireless channels in [15].

Pearson correlation coefficient only measures the linear dependence:

$$\mathbf{E}[X\cdot X^2]=0$$

Definition 6

The lower and upper tail dependence are defined as: $\lambda_L = \lim_{u \to 0} P\left(X_2 \le F_2^{-1}(u) | X_1 \le F_1^{-1}(u)\right)$

$$\lambda_{U} = \lim_{u \to 1} P\left(X_{2} > F_{2}^{-1}(u) | X_{1} > F_{1}^{-1}(u)\right)$$

A D F A B F A B F A B

Empirical Copula

Property 1

$$\lambda_L = \lim_{u \to 0} \frac{C(u, u)}{u}$$
$$\lambda_U = \lim_{u \to 1} \frac{1 - 2u + C(u, u)}{1 - u}$$

Remark 4

Tail dependence provides an approach to quantification of the dependence in extremes of a multivariate distribution and can be related directly to the parameters of the copula statistical model.

One physical scenario is the MIMO system where there is a strong interferer close to the receiver. The interference can be quite impulsive at different time slots, frequency bands and space antennas.

Challenge

Challenge: Choosing the right copula with properties

- Captures the characteristics of the dependence structure, such as symmetry or exchangeability;
- The closure property under the taking of margins, i.e., the bivariate margins or higher-order margins belongs to the same parametric family;
- Flexibility and wide range of dependence which means one can get wide-ranging dependence by varying one or several paramters;
- Tractability, i.e., closed form of representation of marginals and densities or numerically computationally feasible to work with.

Copula Theory

Application of Copulas

- Mutual Information
- Blind Source Separation
- Receiver Design
- Diversity Combining
- Channel Estimation
- Copulas in Signal Processing
- Empirical Copula
- Other Works

3 Challenge

4 Summary & Conclusion

< (日) × (日) × (1)

• Copula serves as a powerful mathematical tool for modeling the dependence structure between random variables;

.

- Copula serves as a powerful mathematical tool for modeling the dependence structure between random variables;
- It is now gradually applied in the academic study of communication area, and has great potential in its application;

- Copula serves as a powerful mathematical tool for modeling the dependence structure between random variables;
- It is now gradually applied in the academic study of communication area, and has great potential in its application;
- The most popular dependence in our previous study is "independence";

- Copula serves as a powerful mathematical tool for modeling the dependence structure between random variables;
- It is now gradually applied in the academic study of communication area, and has great potential in its application;
- The most popular dependence in our previous study is "independence";
- Copula always outperfroms independence even it is independent. Choosing the right copula, "worst" case is independent.
